

# PA – 4 Question Answer Task on Squad

By – Mudit Jain(muditjai@)

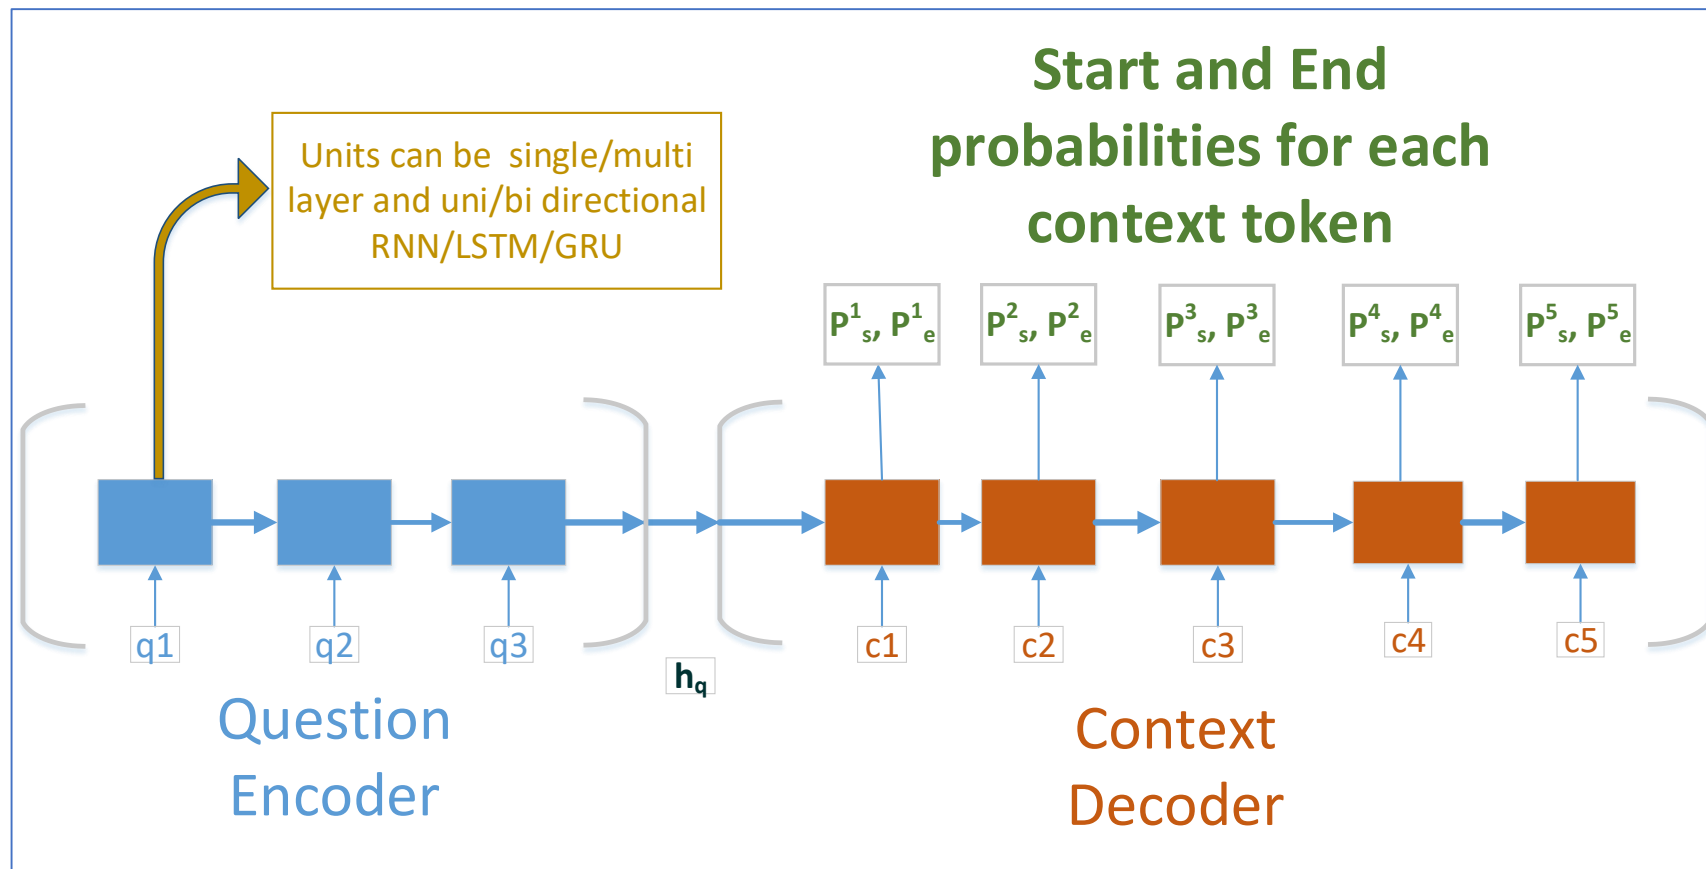

# Introduction to problem and dataset

- Question answering is a challenging sub-problem within machine comprehension area.
- Solving question answering problems can help automate customer care, enable better search in text etc.
- Recently Squad dataset with 100K context, question, answers tuples has been created using Wikipedia and human judgment.
- The problem statement is – Given a context paragraph, and a question, generate an answer span pair  $a_s < a_e$  which answers the question. The performance is measured using F1 score and Exact match(EM) score.

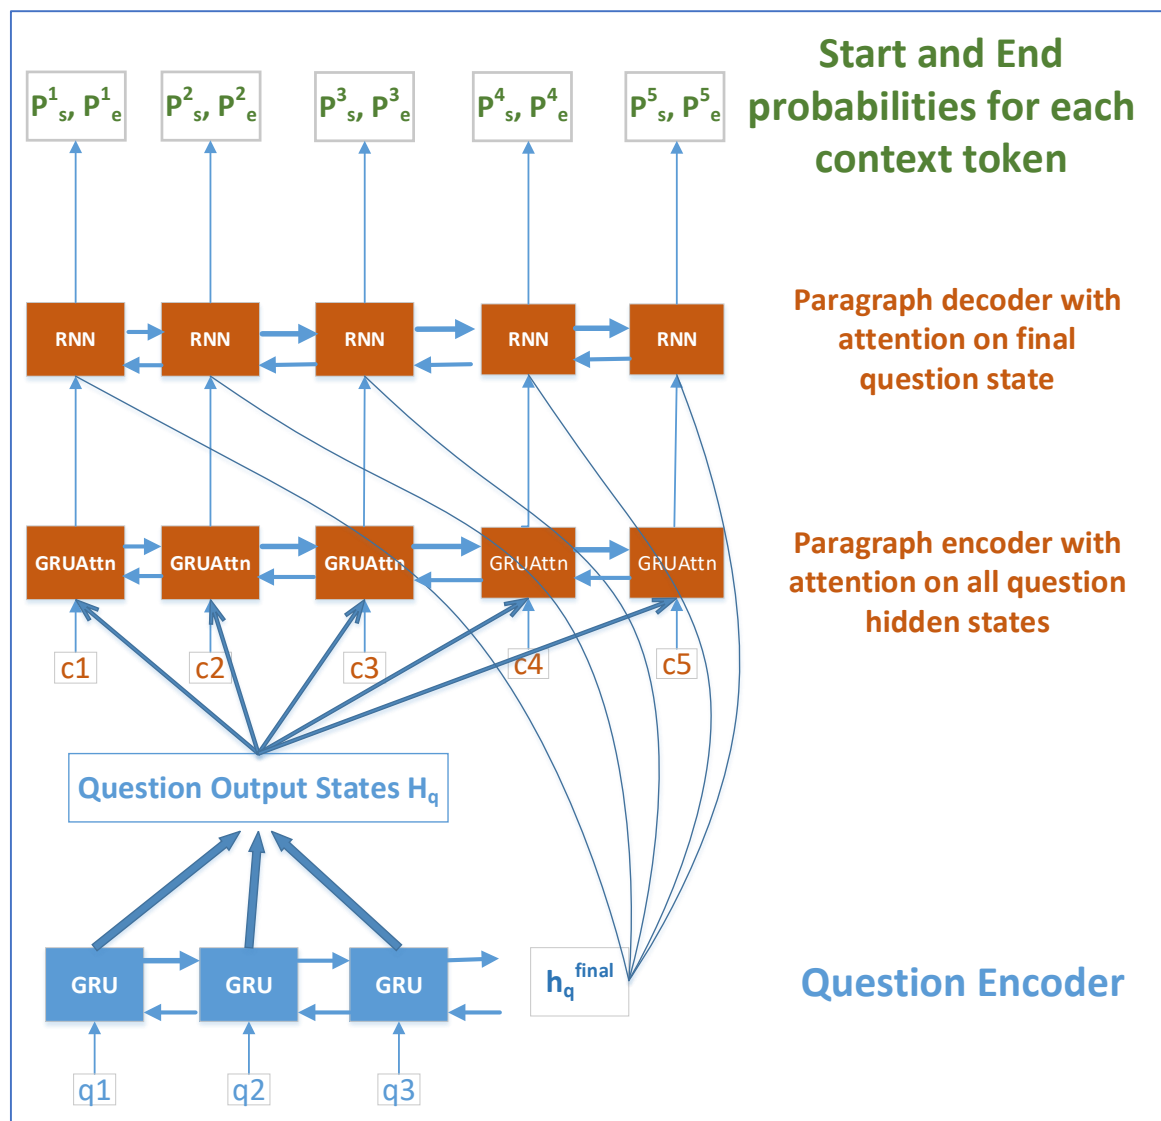

# Solution approaches and conclusions

- Recent research has focused on using various deep learning methods to solve it.
- I have created 3 different NN model for this problem.
- Model 3 with 30/20 as F1/EM score, is able to learn the correct semantics of response ie “Who” type of questions need a person in response, “When” type of questions need a time, “How much” type of questions expect a quantity.
- Questions with simple sentence structures and short simple answers are answered correctly most of the times. Long answers are not answered correctly.
- Even when factually incorrect, the answers are still mostly coherent.

# Model 1 – Simple encoder decoder network

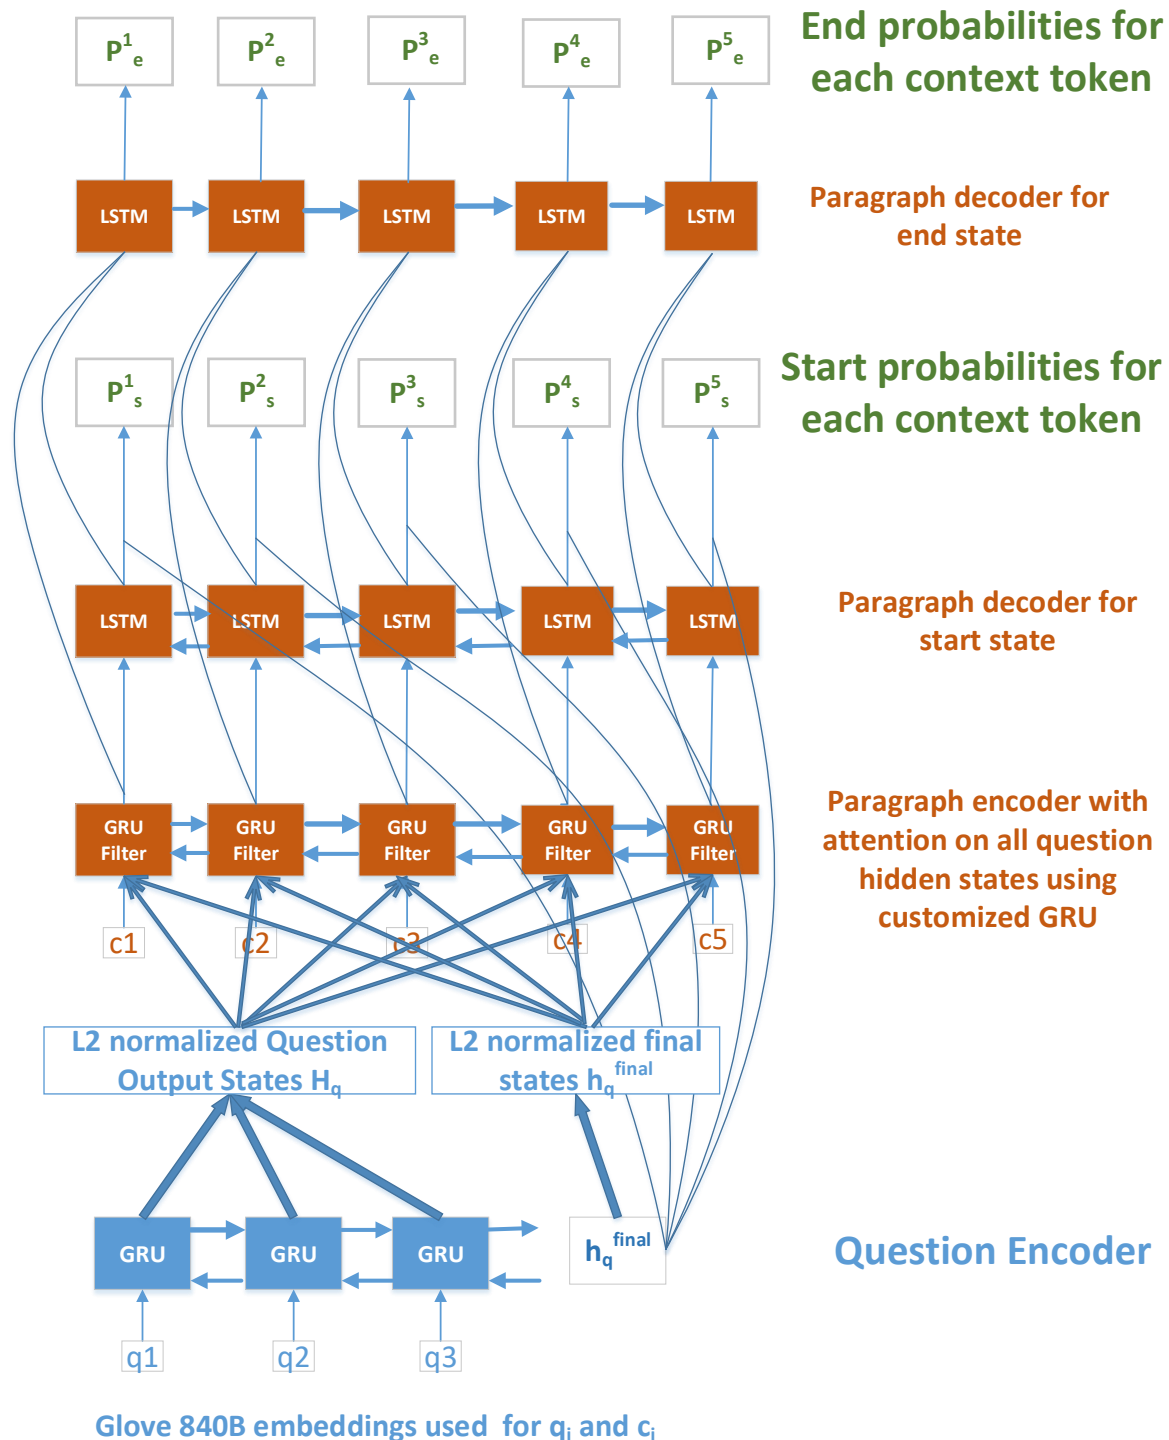

|                        | Sanity Check Set |      | Dev Set |      | Test Set |      |
|------------------------|------------------|------|---------|------|----------|------|
|                        | F1               | EM   | F1      | EM   | F1       | EM   |
| Simple Encoder Network | 3.34             | 0.37 | 5.20    | 0.64 | 4.89     | 0.63 |

## Model 2 – Attention based encoder decoder network

|                               | Sanity Check Set |      |
|-------------------------------|------------------|------|
|                               | F1               | EM   |
| Attention based model epoch 4 | 2.33             | 0.12 |
| Attention based model epoch 8 | 2.27             | 0.12 |

## Model 3 – Filter and Attention based two step decoder network

### GRU Filter Cell

$$\begin{aligned}
 h_p &= \text{GRU}(e_p) \\
 \alpha &= \text{cosine}(h_p, H_q) \\
 h_p^{\text{max\_sim}} &= h_p * \max(\alpha) \\
 h_p^{\text{mean\_sim}} &= h_p * \text{mean}(\alpha) \\
 h_p^{\text{question\_sim}} &= h_p * \text{cosine}(h_p, h_q^{\text{final}})
 \end{aligned}$$

$$\text{gru\_out} = \text{Linear}(h_p^{\text{max\_sim}} h_p^{\text{mean\_sim}} h_p^{\text{question\_sim}} h_q^{\text{final}})$$

## Model 3 Performance

|                            | Sanity Check Set |       | Dev Set |       | Test Set |      |
|----------------------------|------------------|-------|---------|-------|----------|------|
|                            | F1               | EM    | F1      | EM    | F1       | EM   |
| GRU filter<br>attn epoch 1 | 18.90            | 11.23 | 17.65   | 8.24  | 17.36    | 7.89 |
| GRU filter<br>attn epoch 2 | 25.88            | 18.39 | 24.39   | 13.3  | --       | --   |
| GRU filter<br>attn epoch 3 | 28.04            | 20.61 | 28.87   | 17.38 | --       | --   |

Thanks!
